This paper reports the establishment of the Australian species *Austrosalomona falcata* (Redtenbacher, 1891) (Orthoptera: Tettigoniidae) an addition to the New Zealand fauna in Northland. The Australian katydid has been collected from two Northland locations on three occasions - 2007, 2008 and 2011, confirming its survival in New Zealand. Additional distribution records of another Australian, a species of *Pterapotrechus* (Orthoptera; Gryllacrididae) now includes one sighting at Langs Beach, Northland in 2008. This 'winged weta' has previously been reported from Pukekohe since 1990 and Whangapoua on the Coromandel Peninsula in 1997.
